Safe use of opioids in hospitals

While opioid use is generally safe for most patients, opioid analgesics may be associated with adverse effects, the most serious effect being respiratory depression, which is generally preceded by sedation. Other common adverse effects associated with opioid therapy include dizziness, nausea, vomiting, constipation, sedation, delirium, hallucinations, falls, hypotension, and aspiration pneumonia. Adverse events can occur with the use of any opioid; among these are fentanyl, hydrocodone, hydromorphone, methadone, morphine, oxycodone, and sufentanil. While there are numerous problems associated with opioid use, including underprescribing, overprescribing, tolerance, dependence, and drug abuse, this Alert will focus on the safe use of opioids that are prescribed and administered within the inpatient hospital setting. The Joint Commission recognizes that the emergency department presents unique challenges that should also be addressed by the hospital, but may not be directly addressed in this Alert. This Alert will provide a number of actions that can be taken to avoid the unintended consequences of opioid use among hospital inpatients.

Opioid analgesics rank among the drugs most frequently associated with adverse drug events. The literature provides numerous studies of the adverse events associated with opioids. One study found that most adverse drug events were due to drug-drug interactions, most commonly involving opioids, benzodiazepines, or cardiac medications. In addition, a British study of 3,695 inpatient adverse drug reactions found that 16 percent were attributable to opioids, making opioids one of the most frequently implicated drugs in adverse reactions. The incidence of respiratory depression among post-operative patients is reported to average about 0.5 percent. Some of the causes for adverse events associated with opioid use are:

- Lack of knowledge about potency differences among opioids.
- Improper prescribing and administration of multiple opioids and modalities of opioid administration (i.e., oral, parenteral and transdermal patches).
- Inadequate monitoring of patients on opioids.

Of the opioid-related adverse drug events – including deaths – that occurred in hospitals and were reported to The Joint Commission’s Sentinel Event database (2004-2011), 47 percent were wrong dose medication errors, 29 percent were related to improper monitoring of the patient, and 11 percent were related to other factors, including excessive dosing, medication interactions and adverse drug reactions. These reports underscore the need for the judicious and safe prescribing and administration of opioids, and the need for appropriate monitoring of patients. When opioids are administered, the potential for opioid-induced respiratory depression should always be considered because:

- The risk may be greater with higher opioid doses
- The occurrence may actually be higher than reported
- There is a higher incidence observed in clinical trials
- Various patients are at higher risk (see below), including patients with sleep apnea, patients who are morbidly obese, who are very young, who are elderly, who are very ill, and who concurrently receive other drugs that are central nervous system and respiratory depressants (e.g., anxiolytics, sedatives).

* The reporting of most sentinel events to The Joint Commission is voluntary and represents only a small proportion of actual events. Therefore these data are not an epidemiologic data set and no conclusions should be drawn about the actual relative frequency of events or trends in events over time.
The need for assessing and managing pain to help avoid accidental opioid overdose

The safe use of opioids in hospital settings relies on an accurate pain assessment and then applying appropriate pain management techniques.1,2,3 The Joint Commission’s pain management standards have increased awareness of the importance of safe and effective pain management.13 Instituted in 2001, these standards have made a significant difference in appropriate pain management. Before the standards, there were continuing reports of inadequate pain control for postoperative and traumatic pain, cancer pain, and many other acute and chronic pain challenges.13 In addition, compliance with the standards leads to better clinical outcomes, such as improved wound healing, and helps to prevent untoward consequences of inadequate pain relief, such as impaired immune response.14 The importance of both assessing and managing pain is critical to patients who otherwise would suffer debilitating pain. Notwithstanding the need for appropriate pain management, organizations should make staff aware of the following factors and activities that can help avoid accidental opioid overuse:

• Screen patients for respiratory depression risk factors (see sidebar).5,11,12
• Assess the patient’s previous history of analgesic use or abuse, duration and possible side effects to identify potential opioid tolerance or intolerance.
• Conduct a full body skin assessment of patients prior to administering a new opioid to rule out the possibility that the patient has an applied fentanyl patch or implanted drug delivery system or infusion pump.
• Use an individualized, multimodal treatment plan to manage pain.6,15 A multimodal approach combines strategies such as psychosocial support, coordination of care, the promotion of healthful behaviors, nonpharmacologic approaches, and non-opioid pain medications.15,16,17 Upon assessment, the best approach may be to start with a non-narcotic. The Joint Commission recognizes that not all pain can be eliminated; therefore, our standards provide for goal-related therapy. For example, a patient may define a pain level that is tolerable and acceptable on the pain scale (e.g., level three on a 10-point scale).
• Take extra precautions with patients who are new to opioids or who are being restarted on opioids. These precautions should include starting the patient with a short-term trial15 of carefully titrated opioids at the lowest effective dose to achieve satisfactory pain control.18 Sufficient time should be allowed to assess the patient’s response to an initial dose before increasing the dosage or prescribing opioids for long-term use.
• Consult a pharmacist or pain management expert (when available) when converting from one opioid to another, or changing the route of administration (from oral to IV or transdermal). Consider that the patient may be less tolerant of the new drug (incomplete cross tolerance) or that the new drug may be more potent. Note: While there are numerous dose conversion scales and other tools available, each organization should determine the tool(s) that will be used and assess staff’s understanding of the selected tool(s). Sentinel events have been reported to The Joint Commission related to misuse or misunderstanding of these tools.
• Avoid rapid dose escalation of opioid analgesia above routine dose levels in opioid-tolerant patients.
• Take extra precautions when transferring patients between care units and facilities, and

Characteristics of patients who are at higher risk for oversedation and respiratory depression

• Sleep apnea or sleep disorder diagnosis5,6,19
• Morbid obesity with high risk of sleep apnea6
• Snoring5,6
• Older age; risk is o 2.8 times higher for individuals aged 61-70 o 5.4 times higher for age 71-80 o 8.7 times higher for those over age 8013,12,20
• No recent opioid use6,21
• Post-surgery, particularly if upper abdominal or thoracic surgery5,22
• Increased opioid dose requirement6 or opioid habituation
• Longer length of time receiving general anesthesia during surgery6,23
• Receiving other sedating drugs, such as benzodiazepines, antihistamines, diphenhydramine, sedatives, or other central nervous system depressants6,8,12
• Preexisting pulmonary or cardiac disease or dysfunction or major organ failure6
• Thoracic or other surgical incisions that may impair breathing5,6
• Smoker5,6
when discharging patients to their home. Consider that drug levels may reach peak concentrations during transport.

- Avoid using opioids to meet an arbitrary pain rating or a planned discharge date. Dosing should be based on the individual patient’s need and condition.

The Anesthesia Patient Safety Foundation (APSF) and the Institute for Safe Medication Practices (ISMP) and other organizations recommend continuous monitoring of oxygenation and/or ventilation of patients receiving opioids postoperatively.

**Actions suggested by The Joint Commission**

Hospitals can take the following evidence-based actions to help avoid adverse events associated with the use of opioids.

**Effective processes**

1. Create and implement policies and procedures for the ongoing clinical monitoring of patients receiving opioid therapy by performing serial assessments of the quality and adequacy of respiration and the depth of sedation. The organization will need to determine how often the assessments should take place and define the period of time that is appropriate to adequately observe trends. Monitoring should be individualized according to the patient’s response. The assessments are particularly important when the dose has been increased or another type of opioid is administered. In addition to monitoring respiration and sedation, pulse oximetry can be used to monitor oxygenation, and capnography can be used to monitor ventilation. Staff should be educated not to rely on pulse oximetry alone because pulse oximetry can suggest adequate oxygen saturation in patients who are actively experiencing respiratory depression, especially when supplemental oxygen is being used – thus the value of using capnography to monitor ventilation. When pulse oximetry or capnography is used, it should be used continuously rather than intermittently.

2. Create and implement policies and procedures that allow for a second level review by a pain management specialist or pharmacist of pain management plans that include high-risk opioids, such as methadone, fentanyl, IV hydromorphone and meperidine.

3. Create and implement policies and procedures for tracking and analyzing opioid-related incidents for quality improvement purposes.

See relevant Joint Commission requirements: LD.04.01.07 element of performance 1, LD.04.04.05, PC.01.02.01, PC.01.02.03 EP 2 and 3, PI.01.01.01, PI.02.01.01, PI.03.01.01, MM.07.01.03

**Safe technology**

4. If available, use information technology to monitor prescribing of opioids.

- Build red flags or alerts into e-prescribing systems for all opioids. The red flags can be either for dosing limits or alerts, or for verifications.
- Separate sound-alike and look-alike opioids, and use tall man lettering and other techniques to reduce the risk of error.
- Use conversion support systems to calculate correct doses of opioids to help prevent problems with conversions from oral, IV and transdermal routes of administration.
- Use patient-controlled analgesia (PCA) to reduce the risk of oversedation. (See *Sentinel Event Alert #33, “Patient Controlled Analgesia by Proxy,”* for strategies for eliminating risk related to PCA by proxy.) The use of smart infusion pump technology with dosage error reduction software can add another layer of safety.

See relevant Joint Commission requirement: MM.01.01.03

**Appropriate education and training**

5. Advise clinicians who prescribe pain medications to use both pharmacologic and non-pharmacologic alternatives, including multi-modal adjuvant therapies (e.g., physical therapy, acupuncture, manipulation or massage, ice, music therapy). Non-narcotic analgesics, such as acetaminophen, nonsteroidal anti-inflammatory agents, antidepressants, anticonvulsants (e.g., gabapentin and pregabalin), and muscle relaxants (e.g., baclofen, tizanidine), can be used before prescribing an opioid. In addition, when used in combination with opioids, these non-narcotics may reduce the dose of opioids required to effectively manage pain.

6. Educate and assess the understanding of staff that care for patients receiving opioids about the potential effect of opioid therapy on sedation and respiratory depression, the continuum of consciousness, the difference between ventilation and oxygenation, and technological and clinical monitoring. Staff training should emphasize how to assess patients for adverse drug reactions, how to recognize advancing sedation, and the importance of making timely adjustments to the plan of care.
based on the patient’s risk. For example, a comprehensive pain management program can help to educate clinicians, endorse best practices, and improve safety.

7. Educate and provide written instructions to patients who are on opioids (and to the patient’s family or caregiver) about:
   - The various generic and brand names, formulations, and routes of administration of opioids in order to prevent confusion and reduce the accidental duplication of opioid prescriptions;
   - The principal risks and side effects of opioids, including the likelihood of constipation, and the risk of falls, nausea and vomiting;
   - The impact of opioid therapy on psychomotor and cognitive function (which may affect driving and work safety);
   - The potential for serious interactions with alcohol and other central nervous system depressants;
   - The potential risks of tolerance, addiction, physical dependency, and withdrawal symptoms associated with opioid therapy.
   - The specific dangers as a result of the potentiating effects when opioids are used in combination, such as oral and transdermal (fentanyl patches).
   - The safe and secure storage of opioid analgesics in the home.

When providing this information at discharge, also include phone numbers for a contact person to call with questions.

8. Assess the organization’s need for training based on the analysis of reported adverse events, near misses and staff observations. This analysis may be helpful in identifying knowledge gaps and in developing improvement strategies to reduce recurrences.

See relevant Joint Commission requirements: HR.01.04.01 EP 4, HR.01.05.03, HR.01.06.01, MS.03.01.03 EP 2

Effective tools
9. Provide standardized tools that can be used to screen patients for risk factors associated with oversedation and respiratory depression. Among the available screening tools for patients in the acute care setting are the Pasero Opioid-Induced Sedation Scale (POSS) and the Richmond Agitation-Sedation Scale (RASS). Tools that can be used after discharge to help prevent opioid misuse include the Screener and Opioid Assessment for Patients with Pain (SOAPP and SOAPP-R), the Opioid Risk Tool (ORT), and the Screening Instrument for Substance Abuse Potential (SISAP).
